

Slide 1:

Welcome to the presentation on our Data Structure project. Our goal was to create an efficient system for managing orders in a restaurant using data structures. Specifically, we implemented a solution based on linked lists. This presentation will provide an overview of our code structure and highlight key functions.

Slide 2:

The code utilizes linked lists for data management, a fundamental data structure consisting of nodes connected through pointers. We have two types of linked lists: one for the admin order menu and another for customer orders. Linked lists offer dynamic behavior, allowing for efficient insertion, deletion, and traversal of elements. Our code demonstrates various functions for creating, deleting, and displaying elements in the linked lists. Additionally, it includes functionality for calculating and displaying the customer order bill, as well as saving and loading the admin order menu from a file.

Slide 4:

Now let's focus on the functions related to the admin order menu. We have the "createadmin" function, which creates a new admin order menu item by adding an adminnode to the end of the list. The "deleteadmin" function removes an item from the admin order menu based on its item number. The "displayadmin" function allows us to view the admin order menu. We can also save the admin order menu to a file using the "saveAdminMenuToFile" function, and load it from a file using the "loadAdminMenuFromFile" function.

Slide 5:

Moving on to the customer order functions, we have the "createcustomer" function. It creates a new customer order item by adding a customernode to the end of the customer order list. The "deletecustomer" function removes a customer order item based on its item number. The "displaycustomer" function enables us to view the customer order. Finally, the "displaybill" function calculates and displays the bill for the customer order.

Slide 6:

In the main function, we initialize the admin order menu from a file. Then, we provide a menu for both admin and customer order management. For the admin menu, a password is required for access. We

can add, delete, and view admin order menu items. Additionally, we have the option to save the admin order menu to a file.

Slide 7:

To summarize, our code provides a solution for managing orders in a restaurant. It demonstrates features for admin and customer interactions, such as adding, deleting, and viewing order items. It also supports file operations for loading and saving the admin order menu. While this is a basic implementation, further enhancements can be made to improve reliability and user experience. With additional development, the program can be customized to meet specific requirements.

Slide 8:

In conclusion, our Data Structure project showcases the practical application of data structures in efficiently organizing and manipulating data. The use of linked lists offers flexibility and scalability for managing orders in a restaurant or similar setting. By implementing this project, we have gained valuable insights into the importance of data structures in developing efficient systems. Thank you for your attention.
